Fangfrisch (German for "freshly caught") is a sibling of the Clam Anti-Virus freshclam utility. It allows downloading virus definition files that are not official ClamAV canon, e.g. from Sanesecurity and URLhaus. Fangfrisch was designed with security in mind, to be run by an unprivileged user only.

1. License

Copyright © 2020 Ralph Seichter

This file is part of "Fangfrisch".

Fangfrisch is free software: you can redistribute it and/or modify it under the terms of the GNU General Public License as published by the Free Software Foundation, either version 3 of the License, or (at your option) any later version.

Fangfrisch is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See

the GNU General Public License for more details.

You should have received a copy of the GNU General Public License along with Fangfrisch. If not, see https://www.gnu.org/licenses/.

2. Update strategy

Fangfrisch is expected to run periodically, e.g. using cron. Download attempts are recorded in a database and new attempts are only made after the defined age threshold is reached. Fangfrisch will attempt to download digests first (if available upstream), and only retrieve corresponding virus definition files when their recorded digest changes, minimising transfer volumes.

3. Installation

Fangfrisch requires Python 3.7 or newer. The recommended installation method is using the pip command in a virtual Python environment. Here is an example listing of commands for BASH:

3.1. Create home directory

mkdir -p /var/lib/fangfrisch
cd /var/lib/fangfrisch

3.2. Prepare and activate venv

python3 -m venv venv
source venv/bin/activate

3.3. Install via PyPI

pip install fangfrisch

This step will also create an executable launcher script venv/bin/fangfrisch.

4. Installation packages

As an alternative to pip-based installation, there are packages available for the following Linux distributions:

- Archlinux user repository: python-fangfrisch
- Gentoo Linux official repository: app-antivirus/fangfrisch

Should you need support for these packages, please contact the respective Linux distribution maintainers.

5. Configuration

A configuration file is mandatory, uses an INI-File-like structure and must contain a db_url entry. All other settings are optional. However, unless you enable one signature file provider section, Fangfrisch naturally won't do much.

```
# Minimal example configuration, meant for testing.

[DEFAULT]
db_url = sqlite:///var/lib/fangfrisch/db.sqlite
local_directory = /var/lib/clamav

[urlhaus]
enabled = yes
```

- **cleanup**: Cleanup method used for provider sections. Default: **automatic**, alternative: **disabled**. In automatic mode, Fangfrisch will attempt to delete obsolete virus definition files whenever you disable a provider section. Should you disable this option, orphaned files will be left behind, and you need to ensure cleanup by different means.
- **db_url**: Database URL in SQLAlchemy syntax. Mandatory, no default. Typically, a local SQLite database will suffice.
- enabled: Scan this section for URLs? Default: false.
- **integrity_check**: Mechanism for integrity checks. Default: sha256. You can use disabled if the signature file provider offers no checksums.
- interval: Interval between downloads. Defaults are provider-dependent. Values can be expressed in human-readable form (e.g. 12h or 45m). Please respect the limits set by each provider.
- local_directory: Downloaded files are stored here. No default, so the current working directory of the Python process is used. As this can vary depending on how you launch Fangfrisch, it is highly recommended to define an absolute path like /var/lib/clamav instead. You can override this option in provider sections to separate downloads based on origin.
- **log_format**: See Formatter class documentation for details. Fangfrisch uses sensible defaults depending on the selected log method.
- log_level: Choose one of DEBUG, INFO, WARNING (default), ERROR or FATAL.
- **log_method**: Either console (default, meaning stdout/stderr) or syslog. For the latter, you can also specify a **log_target**.
- log_target: The syslog target address. Typical values are /dev/log (local Linux domain socket), localhost or host.domain.tld:udpport. If no target is specified, localhost is assumed. The UDP port number defaults to 514.
- max size: Maximum expected file size. The default is 10MB, but all predefined providers have

individual size limits (see Appendix A). Values are can be expressed in human-readable form (e.g. 250KB or 3MB). Fangfrisch attempts to inspect the content length before downloading virus signature files so as not to download files larger than the defined limit. If providers don't respond with content length information, Fangfrisch will log a warning but download the data anyway.

- on_update_exec: If any files were downloaded during a pass, a command can be executed in after the pass finishes. No default. A typical value is clamdscan --reload.
- on_update_timeout: Timeout for the on_update_exec command, in seconds. Default: 30.

See here for details about the configuration parser and extended interpolation. Section 5.3 provides additional information on how configuration options are interpreted.

5.1. Default providers

Fangfrisch contains internal defaults for the following providers (in alphabetical order):

- Malwarepatrol
- Sanesecurity
- SecuriteInfo
- URLhaus

The internal default values for providers can be used by specifiying enabled = yes in the desired sections. Some providers require additional configuration as shown in the following example.

```
# Example configuration
[DEFAULT]
db_url = sqlite:///var/lib/fangfrisch/db.sqlite
# The following settings are optional. Other sections inherit
# values from DEFAULT and may also overwrite values.
local_directory = /var/lib/clamav
max_size = 5MB
on_update_exec = clamdscan --reload
on_update_timeout = 42
[malwarepatrol]
enabled = yes
# Replace with your personal Malwarepatrol receipt
receipt = abcd1234
[sanesecurity]
enabled = yes
[securiteinfo]
enabled = yes
# Replace with your personal SecuriteInfo customer ID
customer_id = abcdef123456
[urlhaus]
enabled = yes
max_size = 2MB
```

5.2. User-defined providers

Fangfrisch is of course not limited to the internal defaults. You can define as many additional virus definition providers as you like. The following defines a fictional provider:

```
[fictionalprovider]
enabled = yes
integrity_check = md5
interval = 90m
prefix = http://fictional-provider.tld/clamav-unofficial/

# Reference the defined prefix in URL definitions. Values in
# other sections can be referenced using ${section:option}.
url_eggs = ${prefix}eggs.ndb
url_spam = ${prefix}spam.hdb

# Override local file name for url_spam
filename_spam = spam_spam_spam_lovely_spam.db

# Execute command after each fresh download from url_eggs
on_update_eggs = echo Fresh eggs in {path}
```

5.3. Semantics

Fangfrisch will scan enabled sections for lines prefixed with url_ to determine download sources for virus definition files.

- The value of integrity_check determines both the expected filename suffix for digests and the hashing mechanism used for verification.
- Local file names will be determined by parsing URLs, but can be manually overridden. To change the file name for url_xyz, set filename_xyz to the desired value.
- To launch a command after data was downloaded for url_xyz, define on_update_xyz. The command string may contain a {path} placeholder, which will be substituted with the full path of the downloaded file.

6. Preparing the database

After completing the configuration, make sure to create the database structure by running the initdb command. Running --force initdb will drop existing database tables. For SQLite, deleting the database file is also a common method.

```
fangfrisch --conf /etc/fangfrisch.conf initdb
```

WARNING

Fangfrisch should never be run as root, but as an unprivileged user like clamav.

7. Usage

You can display command line arguments as follows:

You can choose among following actions:

- **dumpconf**: Dump the effective configuration to stdout, combining both internal defaults and your own settings. The effective configuration for the example shown in Section 5 is available in Appendix B.
- **dumpmappings**: Dump URL-to-filepath mappings, as recorded in the database refresh log, to stdout. See Appendix C for details.
- **initdb**: Create the database structure. This needs to be run only once, before the first refresh. Using the --force option will drop existing tables from the database.
- **refresh**: Refresh the configured URLs. The **--force** option can be used to override download interval settings.

As stated before, Fangfrisch is typically run using cron. An example crontab looks like this:

```
HOME=/var/lib/fangfrisch
LOG_LEVEL=INFO
# minute hour day-of-month month day-of-week user command
*/15 * * * * clamav venv/bin/fangfrisch -c /etc/fangfrisch.conf refresh
```

8. Support

The project is hosted on GitHub. Before opening tickets or contacting the author, *always* check existing issues first, including closed ones. This is not meant to discourage you; it just saves time and effort for all involved. Please contact the author Ralph Seichter only after having done your "research". Thank you.

8.1. Reporting problems

If you experience problems, please start by trying to figure out underlying issues on your own. Running with DEBUG level logging helps with that. Should your efforts fail, consider filing a GitHub issue. Each issue needs to answer the questions listed below.

If you answer question number 1, 2 or 3 with "no", do not file an issue. Please answer all other questions as detailed as you can, within reason.

- 1. Have you checked the documentation?
- 2. Have you checked all existing issues, including closed ones?
- 3. Have you done your personal best to resolve the issue on your own?
- 4. What exactly did you do?
- 5. What did you expect to happen?
- 6. What happened instead?
- 7. What was your exact setup (operating system, Python core version, Python module versions)?

8.2. Submitting suggestions

The list of questions is shorter, but important nonetheless:

- 1. Have you checked the documentation?
- 2. Have you checked all existing issues, including closed ones?
- 3. Is the feature I am suggesting helpful for more people than just myself?

If you answered "yes" for all questions, please explain your idea as detailed as possible. Use examples, graphics, and whatever else you think would help others to understand your suggestion.

Appendix A: Default configuration

Fangfrisch contains the following internal configuration settings as defaults. All sections are disabled, and entries with the <code>!url_</code> prefix are included for reference only. These represent data sources which either have a high risk of false positives or are not free to use. Enabling a section will not enable these specially prefixed entries.

```
[DEFAULT]
cleanup = automatic
enabled = false
integrity_check = sha256
log_level = WARNING
log_method = console
max_size = 10MB

[malwarepatrol]
interval = 1d
```

```

Appendix C: Database structure

While users can technically access the Fangfrisch backend database directly, its structure and content are considered **private**. They may change at any time, without notice. Related complaints will be filed under SEP, and possibly ridiculed.

C.1. Accessing mappings

In contrast to direct database access, the **dumpmappings** action allows accessing selected parts of database entries in a stable manner. Specifically, it returns 3-tuples (provider name, URL, local file path). Elements are separated by horizontal tabulators to facilitate piping the output into awk or similar utilities. If specified, the provider option is interpreted as a regular expression, and only DB records with matching provider column are returned. That means if you have providers *foo* and

foobar, you need to use anchoring (e.g. ^foo\$) if you only wish to match entries for the former provider. Make sure to use quoting as required by your shell. Example usage:

```
# Print all recorded mappings for the [example] provider section. fangfrisch --conf /etc/fangfrisch.conf --provider '^example$' dumpmappings
```

```
# Delete all files that were downloaded by Fangfrisch.
# DON'T EXECUTE THIS UNLESS YOU REALLY MEAN IT!
fangfrisch --conf /etc/fangfrisch.conf dumpmappings | awk '{print $3}' | xargs /bin/rm
```
